TITLE: Some Construction Defects of Concreting Equipment ("Combines")  
(Nekotoryye konstruktivnyye nedostatki betoniruyushchikh agregatov (kombaynov)

PERIODICAL: Mekhanizatsiya Stroitel'stva, 1957, 14 No.9,  
pp. 20 - 23 (USSR).

ABSTRACT: Ten factories were erected in the Khar'kov area during 1955 and 1956 for manufacturing pre-stressed hollow floor slabs for houses (Rostov-on-Don, Amvrosiyevok, Kishinev, etc.). During 1957, thirty factories were built in various parts of the country. Fig. 1 shows a concreting combine used for the preparation of reinforced pre-stressed concrete floor slabs. Improvements are recommended, such as: the concretor, bunkers and casting mechanisms should be constructed to be movable in a horizontal plane. The insets forming the hollows, the dividing plates and the terminal grooving rods are subjected to constant abrasion from the concrete and can only be used for about 3 months. The cast iron swivel bearings should be substituted by steel bearings. The position of the operator's cabin should be altered to allow him to control the various phases of production. The gripping mechanism for handling the slabs should

Card1/2

Some Construction Defects of Concreting Equipment

100-9-7/11

be reconstructed to ease manipulation of the same. The clamp carrying the slabs should also be modified. The power supply by 2 overhead trolleys is unsafe. An alternative power supply by flexible cables which are protected by a wooden box and freely following the moving concretor is recommended as less dangerous. A bucket of 0.5 m<sup>3</sup> capacity is used for delivery of the concrete mix. A 3 ton capacity telpher lifts the buckets at a rate of 0.12 m/sec. The plant is not working when the buckets are used for filling the bunkers (approx. 30 min/shift). The capacity of the buckets should be increased to 0.8 to 1 m<sup>3</sup> to avoid this delay. The factory is manufacturing hollow floor slabs of the following dimensions: height - 65, 120, 160 and 200 mm; width - 1 m. The VNIIZhelezobeton designed in 1956 a machine for manufacturing slabs with a larger proportion of voids (Fig. 3). An M-50 vibrator with 0.5 kW/ton capacity is inserted into each hollow-forming tube. This vibrator works at a rate of 5 700 r.p.m. Fig. 4 shows a machine used for an alternative method of forming the hollows, without vibration. The output of the factory reaches 2 000 m<sup>3</sup> of hollow floor slabs per month, when 2 shifts are working (1 m wide and 200 mm high). There are 4 figures.

ABSTRACT: The problem of automatic programmed control of the temperature conditions in a periodic chemical reactor is a fundamental one, the solution of which is necessary for the automatization, for example, of the dyestuffs industry. Earlier work using electronic simulation (I. I. Zaslavskiy, A. Ya. Biryukov, Sistemy\* regulirovaniya periodicheskikh protsessov s izmenyayushcheysha strukturnoy skhemoy. Avtomatzatsiya khimicheskikh proizvodstv, 1960, No. 3), in which an attempt was made to synthesize a

new, more effective, control algorithm, revealed good prospects for the use of controllers with logical elements and variable structures. The present paper is devoted to a test of the results of electronic simulation on an experimental industrial control installation making use of zoned logic. A block diagram of this control system is shown in the Enclosure. The controller described in this paper can be used successfully for programming the control of periodic processes. KAPLAR, L.

Rapid determination of zinc in the presence of proteins.  
L.-Törley, Gy. Rády, and L. Kaplár (Tech. Univ., Budapest), *Acta Chim. Acad. Sci. Hung.*, 3, 315-22 (1953) (in German).—The detn. of Zn by actn. of the dithizone with CCl<sub>4</sub> is complicated by emulsion formation in the presence of proteins. If the layer is kept to a min vol., the emulsion is easily broken by adding strips of filter paper and completely absorbing the aq. layer. The CCl<sub>4</sub> layer is poured off and combined with CCl<sub>4</sub> washings of the strips to yield the soln. for the Zn detn. A photometric procedure and a titrimetric procedure are described for the Zn detn. In the latter procedure a known amt. of dithizone is used in the reaction and the zinc is detd. by difference after the amt. of unreacted dithizone is measured by titration with a standard ZnSO<sub>4</sub> soln. These two procedures gave Zn analyses on several Zn insulin preps. in agreement with the results of the U.S.P. procedure.

AUTHOR: Kaplarević, Komnen, Assistant Production Manager  
(Belgrade)

TITLE: Preparation of aluminum foil for electrolytic  
capacitors

PERIODICAL: Tehnika, no. 2, 1960, 313-318

TEXT: The author describes the properties of aluminum foil, used in electrolytic capacitors and the "Frin-Seibold" etching and oxidation process. Aluminum used in electrolytic capacitors which is dependant on a thin film of oxide on the surface of the foil for capacity, must have a purity of 99.85 - 99.99%. An effective increase in the anodic surface will result in greater capacity. Several methods for converting the smooth foil surface into an etched or roughened one, are known... The mechanical method using emery paper and metal brushes increases the capacitor capacity 2-3 times. The chemical method, by which the foil is etched in a suitable solution increases

X

the capacity 4-6 times and even more. According to some data, the most efficient solutions for this purpose are HCl,  $HCl+CuCl_2$  and  $HCl+HNO_3$ . X

The most efficient electrochemical method of aluminum foil preparation is, however, not well known in Yugoslavia and practically not dealt with at all in technical literature. According to the "Frin-Seibold" method shown in Fig. 1, etching and oxidation are carried out in one operation. Having passed the contact roller (2), the foil enters the acid-resistant plastic pickling bath (3) containing hydrofluoric acid solution of a 5 g concentration per liter. The amount of HF is determined by the size of the bath and the concentration of the acid. Due to the formation of aluminum fluoride, adjustment has to be made by taking away some solution and adding more HF. The foil then passes into the acid-resistant 1,000-liter etching bath (4) which is cooled by water circulating through the cooling pipe network inside the bath. This solution contains 80 g/lit of  $AlCl_3$ , 120 g of HCl and water, making up the total of 850 liters. The aluminum chloride has to be free from

Card 2/8

Preparation of aluminum foil for ...

Y/001/60/000/002/002/002  
D241/D303

impurities and crystallized. A constant check has to be kept on the HCl and AlCl<sub>3</sub> in the solution, since due to the active surface increase, the AlCl<sub>3</sub> concentration will increase and active HCl decrease. From the etching bath the foil passes into the rinsing equipment (5) consisting of 2 horizontal, parallel plastic pipes with perforations, through which the water is sprayed onto the moving foil. Then the foil passes through the opening in the wall (6) into the oxidation equipment. The etching and oxidizing equipment is completely separated from each other by this method. The foil passes through rinsing equipment (7), (8) and (9), which ensure that all traces of the etching solution have been removed.

Preparation of aluminum foil for...

D241/D303

Finally the foil is subjected to oxidation in the electrolytic bath. The oxide film is thin and allows the passage of current in one direction only. The chemical nature of the oxide film has not yet been explained. According to some theories it consists of pure crystallized  $\text{Al}_2\text{O}_3$ , of  $\text{Al}_2\text{O}_3\text{xH}_2\text{O}$  or  $\text{Al}_2\text{O}_3\text{x2H}_2\text{O}$ , or of  $\text{Al}_2\text{O}_3\text{x3H}_2\text{O}$  or  $2\text{Al}(\text{OH})_3$ .

S. Lilienfeld maintained that the oxide film consists of aluminum oxide with a small degree of hydration, which results from the presence of hydroxyl groups OH at the end of long molecular chains. The electrolyte for the formation of oxide film contains usually boric acid, ammonium tetraborate, ammonium pentaborate and ammonia in varying degrees of concentration. The main characteristics of these electrolytes are the pH-value and specific resistance. Fig. 4a shows the effect of the thickness of the oxide film and of the current density on the capacity during the oxidation in boric acid.

## Preparation of aluminum foil for...

In practice the dynamic method of foil oxidation is preferred to the static one. L.N. Zahgejm and L. Nikolayev [Abstracter's note: Zahgejm = Yugoslav transliteration] recommend the following formula for calculating the current density at the point where the foil enter the electrolyte

$$I_{\max} = \frac{I}{2b(v) 0.3 + 0.025L}$$

where I is the current intensity in the bath; V, the rate at which the foil moves in cm/sec; b, the width of foil in cm and L, the length of foil in the bath in cm. According to "Frin-Seibold", oxidation can also be carried out in two baths; one (10) is connected to the lower voltage and the other (11) completes the oxidation up to the desired tension, when the working voltage of the capacitor, for which the foil is prepared, is over 300 v. Both baths have built-in heaters (10b) and (11b) to bring the electrolyte to the desired temperature of 80-90°C. The first bath made of stainless steel has also a built-in cooler (10a) and the second, made of pure aluminum.

Card 7/8

21081

D241/D303

Preparation of aluminum foil for...

has a cathode plate (11a). Pure, crystallized  $H_3BO_3$  with small amounts of  $Na_2B_4O_7$  is used.  $H_3BO_3$  has to have the following properties: ion 0-200<sup>247</sup>/kg; sulfate ion - negative reaction; copper ions - negative reaction and moisture 0.5%. The amount of  $H_3BO_3$  in the solution is about 30 g/liter. After oxidation the foil passes from the bath (12) where it is rinsed in distilled water, into the electric drier (13) and finally onto the rack(14) where it is wound onto reels. Although many physical and chemical points of the electrochemical processing of aluminum foil have not yet been explained, the above-described method is widely used with excellent results. There are 6 figures, 1 table and 11 references: 4 Soviet-bloc and 7 non-Soviet-bloc.

TITLE: Assembly of steel structures in the erection of the housing of  
mill 2500

PERIODICAL: Referativnyy zhurnal, Metallurgiya, no. 11, 1961, 16, abstract 11D80  
("Montazhn. i spetsializir. raboty v str-ve", 1961, no. 5, 9-13)

TEXT: It is a report about the great variety of cranes used in the assembly  
of metal structures. According to the assembly plan for the metal structure, the  
entire housing of the mill was divided into 6 parts with assembly operations  
lasting 1.5 - 2.5 months for each part. Of special interest is the assembly of  
riveted crane arches with a 72-m span and weighing 700 tons each. As result of  
clear organization of the work and the complex mechanization, the efficiency in  
the assembly of the metal structure constituted 33 $\frac{1}{4}$  kg/day per worker and 1.7 m<sup>3</sup>  
of preassembled reinforced concrete, which is considerably higher than the  
estimated norms. ✓

TOPIC TAGS: copper determination, lead determination, indium analysis, amalgam, polarography, quantitative transfer, electrolyzer design

ABSTRACT: The essence of the method proposed for the determination of copper and lead in the presence of excess indium consists in carrying out a preliminary electrolytic accumulation in one supporting electrolyte solution and in after separation of the amalgam in another. This technique having certain advantages over others was carried out in order to determine the possibility of a plant for the

Card 1/2

L 28710-65

bismuth, copper, lead, cadmium, indium, and zinc from one solution of alkaline ethylenediamine into another. A new design of an electrolyzer was proposed which makes it possible to transfer the electrodes (and mercury drop) from one electrolyte into the other without breaking the circuit and in an inert medium. Experiments were performed on the quantitative transfer of copper and lead from 1 M  $H_3PO_4$  into an alkaline solution of ethylenediamine. The transfer losses did not exceed 10-15%, which was satisfactory. The following table gives some data obtained. The copper and lead content of the solution was determined by atomic absorption spectrometry. The error of the method is about 5%.

ABSTRACT: Investigations were carried out in order to select a supporting electrolyte solution in which indium would either not be reduced, or be reduced at potentials much more negative than the copper reduction potential. The best supporting electrolyte found was a 0.1M solution of ammonium chloride. The method is based on the polarographic reduction of copper ions at a dropping mercury electrode.

Caro

comparative study was made of the copper troughs obtained in an analysis of indium samples on mercury drops obtained on platinum and silver contacts. More distinct and reproducible copper troughs are obtained by using a silver contact. The error of the copper determination was 15-20%. The copper content of the analyzed indium samples was  $1 \times 10^{-5}$  to  $4 \times 10^{-5}\%$ . Orig. art. has 1 figures.

TITLE: Polarographic determination of trace amounts of copper in indium

SOURCE: Spektral'nye i khimicheskiye metody analiza materialov (Spectral and chemical methods of materials analysis); sbornik metodik. Moscow, Izd-vo Metallurgiya, 1964, 115-118

TOPIC TAGS: polarography, dropping mercury electrode, copper determination, indium analysis

ABSTRACT: An amalgam polarographic method was developed for the determination of  $10^{-5}$ - $10^{-6}\%$  copper in high purity indium without the separation of the base metal. The indium samples were first dissolved in nitric acid and the solution evaporated to dryness. Tests with a variety of acids, such as HCl, HBr,  $HNO_3$ ,  $H_2SO_4$ , and  $H_3PO_4$  in which indium is readily soluble showed that the best results are obtained with 1 M  $H_2PO_4$  which binds a large part of the indium to form irreducible complexes under the analytical conditions. The potential of the anode peak of copper in this base electrolyte is +0.07 and of indium is -0.42 v. It was found that the use of solvents containing  $Cl^-$  and  $Br^-$  ions

Card 1/2

L 14973-65  
ACCESSION NR: AT4048098

2

permits the dissolution time of the indium samples (0.2 g) to be reduced to 15-20 min., but the formation of an insoluble film renders the determination of copper difficult. The samples must be dissolved at 120-150°C; during removal of the excess nitric acid and drying of the precipitated indium nitrate, the temperature must be below 80-90°C. The polarographic investigation is described in detail. The optimum potential was -1.0 v. Typical polarograms of the base electrolyte on 2 types of electrodes are given. Analysis of 15 samples for copper showed a maximum sensitivity with a 0.2 g sample of  $2 \times 10^{-6}$  g after 10 min. of accumulation at 0.14 microamp./cm. The time required for analysis of a blank and two parallel samples with  $10^{-5}\%$  impurity was 2-2.5 hours. "The colorimetric and part of the polarographic analyses were carried out in the factory laboratory by Engineer R. D. Tresnitskaya." Orig. art. has: 2 figures.

TITLE: Development of an improved quick method for determining copper micro-concentrations in high-purity indium by the method of amalgam polarography with accumulation

SOURCE: Ref. zh. Khimiya, Abs. 20G151

REF SOURCE: Izv. Tomskogo politekhn. in-ta, v. 128, 1964, 42-45

TOPIC TAGS: copper; indium, electrolysis, polarography, HIGH PURITY METAL

ABSTRACT: The use of amalgam polarography with accumulation is described for determining microamounts of Cu in high-purity indium. Two grams of indium are dissolved in 1.5 ml 11 N HNO<sub>3</sub> with heating up to 60–50°C. The solution is evaporated to 0.1–0.2 ml, 2 ml 1 M H<sub>3</sub>PO<sub>4</sub> are added, electrolysis is carried out for 6 min, and the anode peak is recorded. The analysis of 3 samples (ea. 2 parallel and 2 control tests) lasts about 6 hr. The method permits determination of  $> 4 \times 10^{-6}$ % Cu. In determining  $2.5 \times 10^{-5}$ % Cu, the standard deviation is  $\pm 14\%$ . G. Prokhorova.

AUTHOR: Stromberg, A. G.; Kaplin, A. A.ORG: Tomsk Polytechnic Institute (Tomskiy politekhnicheskiy institut)

TITLE: Effect of electrode surface and solution volume on the sensitivity of the method of amalgam polarography with accumulation

SOURCE: Zhurnal analiticheskoy khimii, v. 20, no. 10, 1965, 1043-1047

TOPIC TAGS: polarographic analysis, trace analysis, chemical purity, electrode, mercury alloy

ABSTRACT: The article examines the possibility of increasing the sensitivity of the method of amalgam polarography with accumulation by decreasing the volume of the solution. The following expressions are derived:

$$a_0 = 3.8i;$$

$$V_0 = 2.2 \cdot 10^4;$$

$$\frac{S_0}{V_0} = 0.032.$$

Card 1/2

L 14691-66

ACC NR: AP6005676

where  $a_{\infty}$  is the impurity content of a high-purity material (in wt %),  $i_{\infty}$  is the maximum sensitivity of the polarograph,  $V_{\infty}$  is the optimum volume of the solution, and  $S_{\infty}$  is the optimum surface of the mercury electrode. It is thus shown that when standard recording polarographs with a sensitivity of  $10^{-9}$ - $10^{-10}$  A/mm are used, one can determine  $10^{-9}$ - $10^{-10}$ % impurities in high-purity substances if the volume of the solution, surface of the electrode, and certain other conditions are suitably chosen. Deviation from these optimum values causes a decrease in the sensitivity of the method. Orig. art. has: 1 table, 21 formulas.

## TITLE:

Recent Vertical Motion of the Shores of the Far East Seas  
(Sovremennyye vertikal'nyye dvizheniya beregov dal'nevostochnykh  
morey).

## PERIODICAL:

Doklady AN SSSR, 1957, Vol. 116, Nr 6, pp. 1005-1008 (USSR).

## ABSTRACT:

In literature there often appear data about the kind of the recent and not long ago motions of the shores in the Far East and Northeast of the USSR. Frequently, the data about the velocity and direction of these shifting contradict each other, coarsely. Such an estimation apparently has its cause in a) different conceptions of the mechanism of formation of the shore-relief-forms; b) imperfection of the method of investigation and c) an indistinct limitation of the characteristics of not long ago and vertical motions. These latter are defined here. The authors used a uniform theory of method which is in use in the Laboratory for Bottom of Sea- and Shore Relief (of the institute, see below: "association"). Thus, comparable results were rendered possible. Here the theory of method is described shortly. The shores of the Far East Seas are divided according to the kind of their recent

Card 1/3

20-6-31/42

Recent Vertical Motion of the Shores of the Far East Seas.

vertical motions into a number of sections: some are sinking, other are rising; finally there are relative steady sections. The clearest symptoms of the sinking were stated: in the Eastern and Northern part of the Chukot Peninsula ("Chukotskiy poluostrov"), on the Northeastern shore of the Korayken Highland ("Koraykskoye nador'ye") in some sections of the Eastern- and Western shore of Kamchatka, in the surroundings of the town Okhotsk, and at the Northeastern shore of Sakhalin. The raising-zones are: Western shore of the Anadyr Bay, individual sections of the Northeastern- and Eastern Kamchatka, farther the shore of Southern Sakhalin and the Sea Province. The characteristics for the above-mentioned classification are given. In connection with post-glacial transgression all shores of the Far East Seas have an ingressional appearance. But that does not mean a recent shore-sinking, because at the raising shores the eustatic raising of the level was not compensated by tectonic motions. Therefore the observed raising is not relative, but absolute. Low sinking or stability of individual shore sections are to be estimated relatively. They form an algebraic term of a sum of the eustatic raising of the world ocean during the late glacial period and tectonic motions of the continent. No sections with high velocities
